Homework 2

3.5 When a process creates a new process using the `fork()` operation, which of the following states is shared between the parent process and the child process?

ANSWER:

c. Shared memory segments. Processes can only share read-only memory or create shared-memory regions of safe memory(I was confused by the latter but you mentioned this in class. The book was unclear on this point). It would make no sense for the processes to share a stack or heap.

3.9 Describe the actions taken by a kernel to context-switch between processes.

ANSWER:

Say we have two processes P_1 and P_2 . Their process control blocks reside in memory and the values of the CPU will change depending on which process is currently executing. A context is the mechanism used for switching the CPU from the context of one process to the context of another. When the operating system switches from the execution of $P_1 \rightarrow P_2$ and again when the operating system switches from the execution of $P_2 \rightarrow P_1$. This operation can be expensive. There are both direct and indirect costs. The direct cost includes cycling for loading and storing of instructions. The indirect costs from cold cache(cache misses).

In modern CPUs there exists a cache hierarchy. Accessing this cache is many

orders of magnitude faster than accessing memory. Using our P_1 , P_2 process from before. Say the data for P_1 is in the cache, we would say in this case that the cache is hot but say we context switch $P_1 \rightarrow P_2$ and we need to access the data for P_2 which is not in the cache. In this case we would say the cache is cold. Not only do we need to retrieve the data for P_2 and put it into the cache but we need to replace the data for P_1 in the cache with that of P_2 .

Long story short, having a cold cache sucks. The hotter your cache, the smoother your OS operates so limiting the number of context switching is optimal.

3.10 Construct a process tree similar to Figure 3.8. To obtain process information for the UNIX or Linux system, use the command `ps -ael`.

```

1  #include <sys/types.h>
2  #include <stdio.h>
3  #include <unistd.h>
4  #include <sys/types.h> // The book forgot to include
5  #include <sys/wait.h> // these libraries? *tsk tsk*
6  int main() {
7      pid_t pid, pid1;
8      /* fork a child process */
9      pid = fork();
10     if (pid < 0) { /* error occurred */
11         fprintf(stderr, "Fork Failed");
12         return 1;
13     } else if (pid == 0) { /* child process */
14         pid1 = getpid();
15         printf("child: pid = %d", pid); /* A */
16         printf("child: pid1 = %d", pid1); /* B */
17     } else { /* parent process */
18         pid1 = getpid();
19         printf("parent: pid = %d", pid); /* C */
20         printf("parent: pid1 = %d", pid1); /* D */
21         wait(NULL);
22     }
23     return 0;
24 }

```

Use the command `man ps` to get more information about the `ps` command. The task manager on Windows systems does not provide the parent process ID, but the process monitor tool, available from [technet. microsoft.com](http://technet.microsoft.com), provides a process-tree tool.

ANSWER:

```

978 2053 1084 1084 ? -1 SL 1000 0:00 \_ /usr/lib/gnome-terminal/gnome-terminal-server
2053 2060 2060 2060 pts/4 21519 Ss 1000 0:00 | \_ bash
2060 21519 21519 2060 pts/4 21519 S+ 1000 0:00 | | \_ ./a.out
21519 21520 21519 2060 pts/4 21519 R+ 1000 0:16 | | | \_ ./a.out
2053 21531 21531 21531 pts/11 21565 Ss 1000 0:00 | | \_ bash
21531 21565 21565 21531 pts/11 21565 R+ 1000 0:00 | | \_ ps axjf
978 2098 1084 1084 ? -1 SL 1000 0:00 \_ /usr/lib/gvfs/gvfsd-network --spawner :1.3 /org/gtk/gvfs/exec_spaw/1
978 2126 1084 1084 ? -1 SL 1000 0:00 \_ /usr/lib/gvfs/gvfsd-dnssd --spawner :1.3 /org/gtk/gvfs/exec_spaw/5

```

I apologize if it's tiny but we can clearly see that my program generated a child from a parent. The parent has a PID of 21519 while the child has a PPID of that is the same.

3.12 Including the initial parent process, how many processes are created by the program shown in Figure 3.32?

ANSWER:

So at each iteration of the loop we fork() we fork once. This will make 4 parents. This process creates a binary tree which gives us the following equation for the problem: $\sum_{i=0}^3 2^i + 1 = 2^4 - 1 + 1 = 16$.

3.13 Explain the circumstances under which the line of code marked printf("LINE J") in Figure 3.33 will be reached.

ANSWER:

If the process generated from fork() is a child then this line will have been reached. There must have been an error to reach this stage.

3.14 Using the program in Figure 3.34, identify the values of pid at lines A, B, C, and D. (Assume that the actual pids of the parent and child are 2600 and 2603, respectively.)

```

hermes@hermes-VirtualBox:~$ ./a.out
parent: pid = 28176

parent: pid1 = 28175

child: pid = 0

child: pid1 = 28176

hermes@hermes-VirtualBox:~$

```

3.17 Using the program shown in Figure 3.35, explain what the output will be at lines X and Y.

ANSWER:

Whenever a child is produced it generates $0*(-0)$ then $1*(-1)$ then $2*(-2)$ then $3*(-3)$ then $4*(-4)$ producing:
 $X = \{0, -1, -4, -9, -16\}$

Whenever a parent is produced it generates the following list:
 $Y = \{0, 1, 2, 3, 4\}$

Extra Credit

The following exercise is optional and it has two project points: We discussed this function in class. It forks and runs a program. Make an independent program of this code and name it “execute”. Use “execute” to run your “copy” program. Make the necessary changes in the given code.

ANSWER:

I will include the file I used to produce this output as well. I didn’t like the code included from the book. I felt it was clunky and over complicated so I wrote my own. Thank you and I hope you have a good day whenever you get to this. :)

```
10  int main (int argc, char *argv[]) {
11      pid_t c_pid = fork();
12      int status;
13      if (c_pid < 0) {
14          perror("There was an error with the fork.\n\n");

```

PROBLEMS OUTPUT DEBUG CONSOLE TERMINAL 1: bash

```
hermes@hermes-VirtualBox:~$ gcc -o execute execute.c
hermes@hermes-VirtualBox:~$ ./execute copy BACKING_STORE.bin TEST.bin
The child PID for the process is is 3260

The PID for the process is is 3260

The process 3260 exited with the status 0

hermes@hermes-VirtualBox:~$
```
